

## Advanced Data Structures

Spring Semester 2017

### Exercise Set 13

We aim at designing succinct datastructure for storing *trits* (3-state version of bits). In particular, we want to store  $X \in \{0, 1, 2\}^n$  using  $\log_2 3 \cdot n$  bits + small overhead, having fast access to any  $X[i]$ .

**Exercise 1:**

Show that  $\Theta(w)$  trits can be stored with  $\mathcal{O}(1)$  overhead, providing  $\mathcal{O}(1)$  time access.

*Hint:* Interpret  $X \in \{0, 1, 2\}^n$  as  $X \in [0 .. 3^n - 1]$ .

**Exercise 2:**

Show that  $n$  trits can be stored using  $\lceil \log_2 3 \cdot n \rceil + \mathcal{O}\left(\frac{n}{w}\right)$  bits, providing  $\mathcal{O}(1)$  time access.

**Exercise 3:**

Show that  $n$  trits can be stored using  $\lceil \log_2 3 \cdot n \rceil + \mathcal{O}\left(\frac{n}{wt}\right)$  bits, providing  $\mathcal{O}(t)$  time access, for any  $1 \leq t < n/w$ .

All previous exercises are based around idea that any coding from universe  $X$  uses  $\lceil \log_2 |X| \rceil$  bits, which wastes  $\mathcal{O}(1)$  bits (unless  $|X|$  is power of two).

**Definition.** For any universe  $X$ , and appropriately chosen integers  $K, M$ , an injection  $X \rightarrow 2^{[M]} \times [K]$  is called *spill-over representation* of  $X$ . For any  $x \in X$ , the value of  $k \in [K]$  from its representation is called its *spill*.

**Exercise 4:**

Show, that for any  $X$  and  $r < |X|$ , there is a spill-over representation of  $X$  with  $r \leq K \leq 2r$  such that  $|X| \leq K \cdot 2^M \leq \left(1 + \frac{1}{r}\right)|X|$ . Moreover, show that encoding/decoding can be done with few arithmetic operations.

Spill-over representation wastes only  $\log_2(1 + 1/r) = 1/\mathcal{O}(r)$  bits.

**Exercise 5:**

Show that  $n$  trits can be stored using  $\lceil \log_2 3 \cdot n \rceil + \mathcal{O}\left(\frac{n}{w^2/\log w}\right) + \text{polylog}(n)$  bits, providing  $\mathcal{O}(1)$  time access.

*Hint:* Take  $r$  to be constant to be fixed later. Use two-level scheme:

- On the first level, store  $\Theta(w)$  trits in spill-over representation, for some  $K \in [r .. 2r]$ . Keep bits on this level.
- On the second level, store spills, grouped in the same way as trits in Exercises 1-3.

Count the number of bits wasted in each place.

**Exercise 6:**

Generalize previous Exercise into:  $\lceil \log_2 3 \cdot n \rceil + \mathcal{O}\left(\frac{n}{w^t}\right) + \text{polylog}(n)$  bits for  $n$  trits, with  $\mathcal{O}(t)$  time access (for constant  $t$ ).

**Exercise 7:**

Show that data structures from all previous exercises support writes in the same time as reads.
