3.4.17

Topic: Dynamic Graphs I

- Operations: Insert/Delete Edges  
Connectivity  $(u, v)$
- Flavour: Fully Dynamic  
Partially: - Incremental  
- Decremental

Trees: •  $O(\log n)$  worst case / op  
fully dynamic.

- $O(1)$  amortized  
decremental (Eppstein et al. 96)

old, at least  
not young

Plane graphs:  $O(\log n)$

## General Graph :

- Hope  $O(\log^{O(1)} n) / op$
- $O(\log^2 n)$  update  
 $O(\log^n / \log \log n)$  query
- $O(\sqrt{n})$  update } Eppstein et. al. 97  
 $O(1)$  query }
- $O(n^{0.49})$  update Wulf - Nielsen 2017

Decremental :  $O(m \log n + \text{poly}(\log(n))n + \# \text{queries})$

Incremental : Union - Find D.S.

$O(\alpha(m, n)) / op \quad \sim 1975$   
 $\uparrow$  Inverse A.

Lowerband: Update or Query needs  $\Omega(\log n)$

# Dynamic Connectivity on Trees

Approach      Link-Cut-Trees

Euler Tour Trees

## Euler Tour Tree:

• MAKE\_TREE( $v$ ): New isolated tree       $\cdot v$

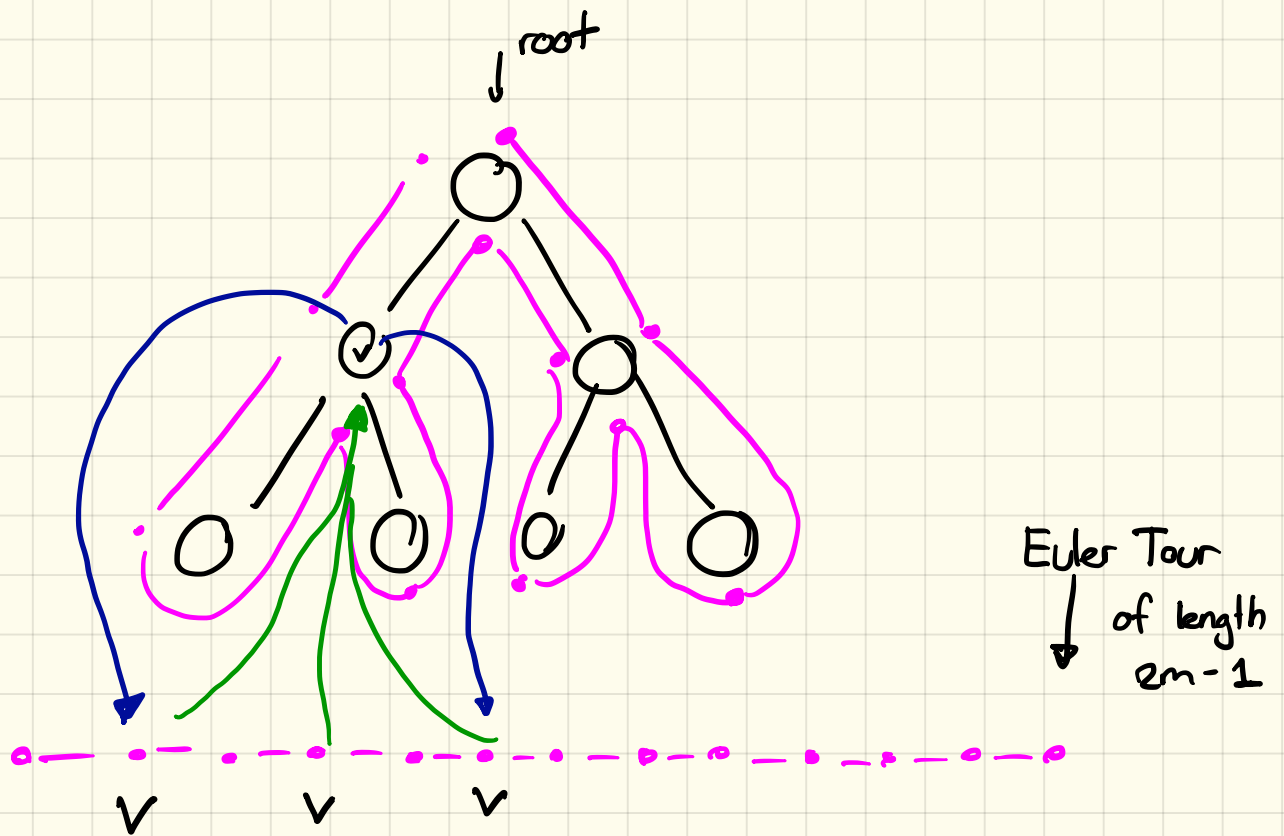

• Link( $u, v$ ):

• Cut( $v$ ): Delete edge ( $v, \text{parent}(v)$ )

• Find-Root( $v$ )

Idea      maintain Euler tour  
                around the tree

→ Build Balanced Binary Search Tree on Euler Tour ordered by order in tour.

Find Root( $v$ ):

- Start in first visit to  $v$  on tour

- Walk up to root of BST
- Walk Left to  $r$

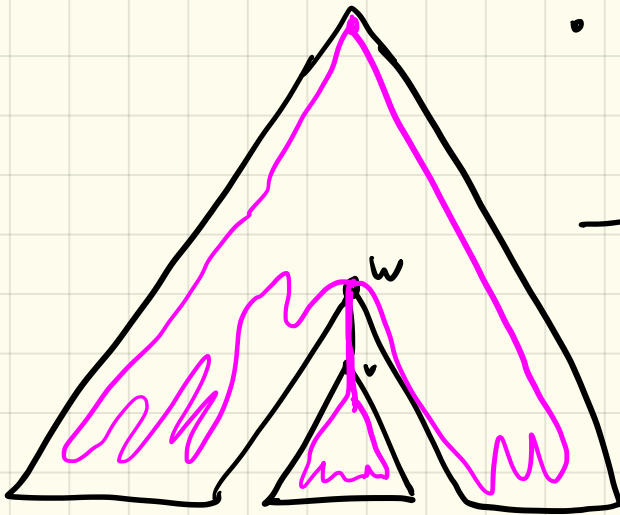

- Make\_Tree( $v$ ): 'trivial'

- Cut( $v$ ):

- Split of BST in  $O(\log n)$

- Remove one  $w$  in  $O(\log n)$

- Link( $v, w$ ):

- Add one  $w$

- Merge BST

Note: If  $v$  is not a root, one can make it root!

- Connectivity( $v, w$ ) =

Find-Root( $v$ )  $\stackrel{?}{=}$  Find-Root( $w$ )

Possible Augmentation of nodes  
(min, max, sum) between first & last visit.

Fully Dynamic Graphs Holm et. al

$O(\log^2 n)$  amortized time

Idea: Maintain Spanning Forest

Problem Deletion of Edge in SPT

→ Hierarchically divide connected components of  $G$

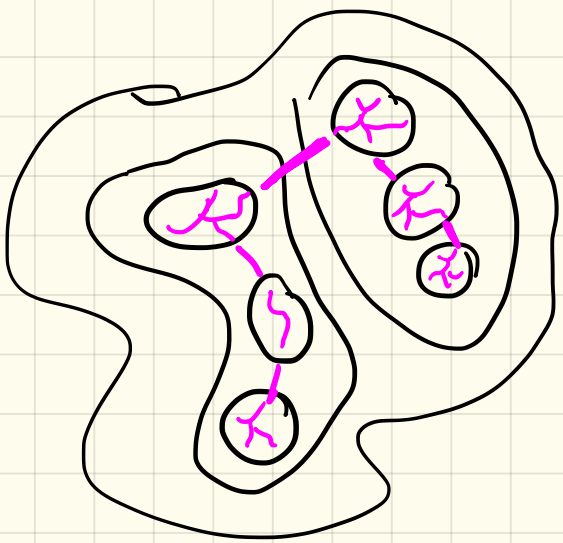

- $\lceil \log n \rceil$  levels of edges partition of  $E$

$G_i$  = subgraph of  $G$  of edges level  $\leq i$

$$G_0 \subseteq G_1 \subseteq \dots \subseteq G_{\log n} = G$$

Invariant 1 Every connected component of  $G_i$  has size  $\leq 2^i$  (vertices)

$F_i$  = spanning forest of  $G_i$

Invariant 2

$$F_i \stackrel{!}{=} F_{\log n} \cap G_i$$

Query: Euler tour tree query on  $T_{\log n}$

Insert ( $e = (v, w)$ ):

- Add  $e$  to incidence lists of  $v, w$
- $e$  level =  $\log n$
- If  $v, w$  were disconnected, add  $e$  to  $T_{\log n}$   
(re-root to  $v$ )

Delete ( $e = (v, w)$ )

- Remove  $e$  from incidence lists
- If  $e \notin T_{\log n} \rightarrow$  Done
- If  $e \in T_{e\text{-level}} \rightarrow e\text{-level}$

- delete  $e$  from  $T_{e\text{-level}}, \dots, T_{\log n}$
- if there is a replacement edge,  
at level  $x$  it is good on  
 $T_x, \dots, T_{\log n}$

For  $i = e\text{-level}, \dots, \log n$

$T_v, T_w$  be the trees of  $F_i$  containing  $v, w$

w.l.o.g.  $|T_v| \leq |T_w|$  — here we need size info of ETT

$$|T_v| + |T_w| \leq 2^i \Rightarrow |T_v| \leq 2^{i-1}$$

⇒ Can "afford" to push  $T_v$  into  $i-1$  level. ) ?

For each edge  $e' = (x, y)$  with  $x \in T_v$  and level  $i$

IF  $y \in T_w$  : add  $e'$  to  $F_i, \dots, F_{\log n}$

and STOP

ELSE :  $e'$ -level =  $i-1$  since  $y \in T_v$

add  $e'$  to  $F_{i-1}$
